

# Multi-Patch Geometries

This is referred to as a ***single patch*** geometry, as the geometry is composed using a single NURBS map.

The single NURBS map takes the patch from *parametric space* to *physical space*.

For this configuration, it is impossible to use a single NURBS map to parameterize the geometry. Instead, we use ***multiple patches***.

For *each patch* in *physical space*, there is a *corresponding  $\mu$*  in *parametric space*. A single NURBS mapping then takes the patch back and forth from parametric space to physical space.

To ensure a ***watertight*** geometry, we must ensure that the patches meet ***parametrically*** and ***geometrically*** on the internal faces where they meet.

To ensure a ***watertight*** geometry, we must ensure that the patches meet ***parametrically*** and ***geometrically*** on the internal faces where they meet.

This requires that the ***control nets*** on opposing faces are coincident.

All of the aforementioned machinery may be extended to the mult patch setting. In fact, the element extraction operators are *unchanged*.

All of the aforementioned machinery may be extended to the mult patch setting. In fact, the element extraction operators are ***unchanged***.

The patch-wise IEN arrays are modified using a ***master-slave*** relationship at the patch interfaces. See notes for more details.
